Gaia

Robust Semantic Segmentation for Off-Road Autonomy

Bridging Synthetic Learning with Real-World Terrain Intelligence

Can a model trained only on synthetic data understand the real world?

TEAM: ADILAQUIL2005

DEVCATION 2026

Made with GAMMA

The Problem

Off-road autonomy demands precise, real-time scene understanding — but building reliable systems is harder than it sounds. Three core challenges stand in the way:

Domain shift between synthetic and real-world environments is the primary bottleneck in off-road autonomy.

📍 Scene Understanding

Off-road environments are visually complex — rocks, grass, bushes, and terrain blend together without clear boundaries, making accurate segmentation extremely difficult.

💰 Data Scarcity

Real-world labeled data is expensive, time-consuming to collect, and dangerously limited. Annotating pixel-level terrain at scale is simply not feasible for most teams.

⚠️ Domain Shift

Models trained on one environment catastrophically fail when deployed in unseen terrains. This **domain shift** is the defining barrier to real-world off-road autonomy.

Made with GAMMA

Objective

Gaia was designed with a single north star: train entirely on synthetic data and generalize to real-world environments — without ever seeing them during training.

IoU (Intersection over Union) measures how accurately predicted segmentation overlaps with ground truth — the gold standard metric for semantic segmentation quality.

Train on Synthetic Data

Leverage Falcon-generated synthetic desert environments to build a diverse, richly labeled training corpus at zero annotation cost.

Generalize to Unseen Worlds

Validate the model's ability to transfer learned representations to entirely new, real-world terrain distributions it has never encountered.

Maximize IoU

Optimize specifically for **Intersection over Union (mIoU)** — the gold standard metric for semantic segmentation quality and per-class coverage.

Made with GAMMA

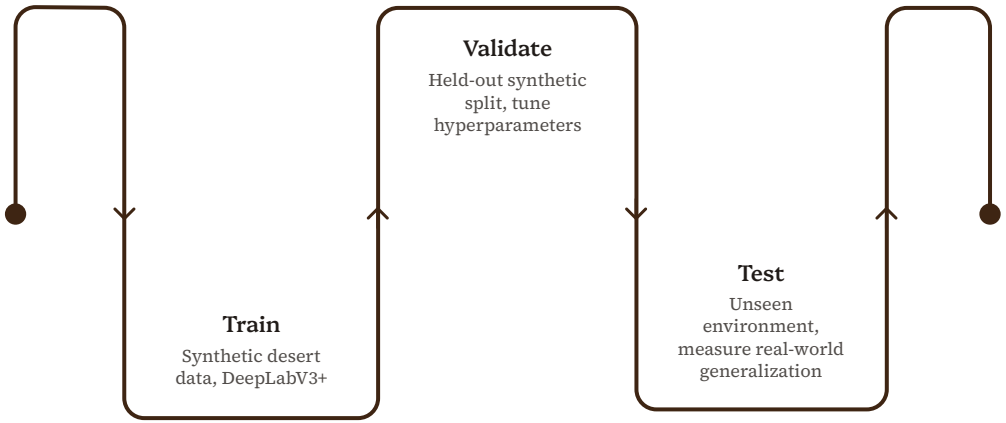
Approach Overview

Synthetic Dataset

All training data sourced from **Falcon-generated** synthetic desert environments — photorealistic, fully labeled, and infinitely scalable without manual annotation.

Design Philosophy

Rather than chasing the largest model, Gaia prioritizes **robustness and generalization** — building a pipeline that holds up when the terrain changes unexpectedly.



The end-to-end pipeline is clean and deliberate — each stage designed to stress-test the model's ability to generalize beyond its training distribution.

Made with GAMMA

Model & Methodology

Gaia is built on a battle-tested architecture, carefully configured for multi-class off-road terrain segmentation with aggressive augmentation to simulate real-world variability.

🧠 Architecture

DeepLabV3+ with a ResNet-50 backbone — chosen for its atrous convolution and strong encoder-decoder design, delivering high-resolution semantic maps.

🎯 Segmentation Classes

10-class remapped label set covering sky, ground, vegetation, rocks, logs, and more — carefully balanced to reflect real desert terrain diversity.

📉 Loss Function

Hybrid loss: **0.5 × Cross-Entropy + 0.5 × Dice Loss** — combining pixel-level accuracy with overlap optimization for better boundary delineation.

Augmentation Strategy

To bridge the synthetic-to-real gap, a comprehensive augmentation pipeline was applied during training:

- Brightness & Contrast
- Gaussian Noise
- Geometric Transforms

Made with GAMMA

Training Performance

Gaia's training curve tells a clean story: consistent loss reduction with no signs of overfitting — a hallmark of a well-regularized, generalizable model.

0.3226

Train Loss

Final training loss after full convergence across all epochs.

0.2993

Val Loss

Validation loss — lower than train loss, confirming strong generalization and no overfitting.

✅ Validation loss tracking below training loss throughout — a strong indicator of a stable, well-regularized training run with no overfitting behavior.

Made with GAMMA

Key Results

Gaia delivers compelling segmentation performance — and crucially, it **outperforms the baseline U-Net by a significant margin** despite zero real-world training data.

Validation mIoU

58.01%

Strong in-distribution performance on held-out synthetic validation split.

Test mIoU

30.92%

Despite significant domain shift from synthetic training to real-world environments, the model retains meaningful segmentation capability without any real-world training data — demonstrating robust generalization.

Baseline U-Net

<20%

Gaia outperforms the U-Net baseline by **more than 10 percentage points** on test mIoU.

> → Strong generalization despite significant domain shift from synthetic training to real-world test environments.

Per-Class IoU Breakdown

Key insight: The model performs strongly on large-scale structural classes (sky, landscape) but struggles with fine-grained, visually similar objects (logs, flowers, ground clutter).

Class	IoU	Performance
Sky	0.9764	⭐ Excellent
Landscape	0.6432	✅ Strong
Dry Grass	0.4551	✅ Good
Dry Bushes	0.3194	🟡 Moderate
Trees	0.3186	🟡 Moderate
Rocks	0.0267	🔴 Weak
Lush Bushes	0.0005	🔴 Near Zero
Ground Clutter	0.0000	🔴 Undetected
Flowers	0.0000	🔴 Undetected
Logs	0.0000	🔴 Undetected

What the Data Tells Us

Gaia achieves high IoU on **large-scale, structurally distinct classes** — particularly sky (97.6%) and landscape (64.3%) — indicating strong representation learning for dominant scene components.

Performance degrades sharply on **fine-grained, visually similar classes** — including logs, flowers, and ground clutter — which remain effectively unsegmented due to limited separability and severe class imbalance.

Root Cause

The model exhibits bias toward dominant classes due to class imbalance in the synthetic dataset. Rare classes are underrepresented, reducing recall on low-frequency categories and increasing confusion among visually similar subclasses. Class balancing and focal loss are the highest-priority mitigations for v2.

Made with GAMMA

Visual Results & Failure Analysis

Qualitative inspection reveals where Gaia excels and where it struggles — failures cluster around visually similar fine-grained categories.

✅ Where Gaia Wins

Sky, open terrain, and large landscape regions are segmented with near-perfect accuracy. Structural boundaries are sharp and spatially coherent across frames.

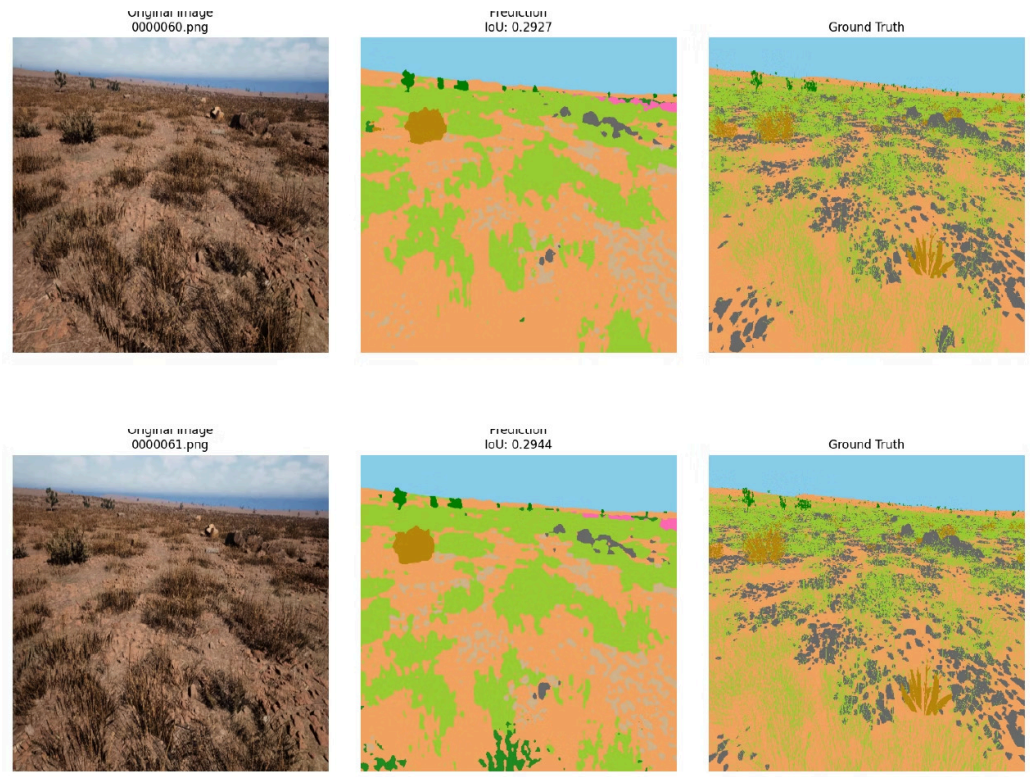
⚠️ Grass vs. Bushes Confusion

Dry grass and dry bushes share very similar color and texture profiles, causing the model to conflate the two — especially in mixed-vegetation regions.

⚠️ Logs vs. Rocks Confusion

Both logs and rocks appear as dark, irregular shapes on the ground plane. With near-zero training representation, the model defaults to the dominant "rocks" label.

Prediction Example 1



Made with GAMMA

Conclusion & Future Work

What We Built

- **58% validation mIoU** — strong generalization from synthetic training data to unseen environments
- Robust, reproducible **end-to-end pipeline** for off-road semantic segmentation
- **Real-world applications:** Unmanned Ground Vehicles (UGVs), field robotics, autonomous navigation in unstructured terrain

Roadmap: Gaia v2

01

Class Balancing + Focal Loss

Address rare-class blindness in logs, flowers, and ground clutter

02

SegFormer (Transformers)

Upgrade backbone to vision transformers for richer global context

03

TTA + Higher Resolution

Test-time augmentation and full-resolution inference for fine-grained detail

> From synthetic simulation to real-world intelligence — **Gaia bridges the gap.**
